

A nitride based strategy solid electrolytes batteries

What are nitride solid-state electrolytes?

Nitride solid-state electrolytes (SSEs) hold significant potential for addressing critical interfacial issues between SSEs and lithium metal in all-solid-state lithium metal batteries. These batteries are at the forefront of energy storage and materials science, and they promise to revolutionize electric vehicles.

Why is lithium nitride a good candidate for SEI construction?

Owing to Li_3N having a high ionic conductivity and being stable against lithium anodes, it is a favorable candidate for SEI construction (Fig. 1c). Furthermore, some organic or inorganic compounds working together with Li_3N may improve the interface to inhibit the growth of lithium dendrites. 3. Properties of lithium nitride

Does lithium nitride suppress the growth of dendrites during electrodeposition?

However, the growth of dendrites during electrodeposition still significantly hinders the practical application of lithium metal batteries. Lithium nitride (Li_3N) modification of the surfaces of Li anodes is regarded as an effective strategy to suppress the growth of lithium dendrites.

What is an all-solid-state lithium battery?

The all-solid-state battery employing an LZC-N0.15 electrolyte and a LiCoO_2 cathode delivers a high discharge capacity of 218.4 mAh g⁻¹ at 4.62 V. All-solid-state lithium batteries are widely regarded as the most promising next-generation energy storage technology due to their exceptional combination of high energy density and intrinsic safety.

Does lithium nitride decompose if matched with an SSE?

The oxidation potential of Li_3N is only 0.5 V, which means that lithium nitride will tend to decompose and thus fail if the electrochemical potential exceeds 0.5 V when matched with an SSE. In this review, many successful cases of constructing Li_3N -based SEIs/ASEIs on the surfaces of Li metal anodes are summarized carefully.

Can lithium nitric halides prevent adverse reactions with lithium anodes?

A series of lithium nitric halides in the $\text{Li}_{3a+b}\text{N}_a\text{X}_b$ ($\text{X} = \text{Cl}, \text{Br}, \text{or I}$) systems have been identified as potential candidates for SEIs to prevent detrimental reactions with lithium anodes. The $\text{Li}_{3a+b}\text{N}_a\text{X}_b$ systems consist of alternating layers of lithium nitrides and halides.

Abstract Sulfone-based electrolyte (SL) as a novel type electrolyte for lithium-ion batteries (LIBs) has attracted increasing attention due to its exceptional high-voltage stability ...
